GPU Programming in Computer Vision

Thomas Möllenhoff, Robert Maier,
Mohamed Souiai, Caner Hazırbaş

Optimization

Technical University Munich, Computer Vision Group
Winter Semester 2014/2015, March 2 – April 3

Outline

- Branch Divergence
- Pitch Allocation for 2D Images
- Host-Device Memory Transfer
- Occupancy

- See the Programming Guide for more details

BRANCH DIVERGENCE

Branch Divergence

- All 32 threads in a warp execute the same instruction
  - always, no matter what

```
__global__ void kernel (float *result, float *input)
{
    int i = threadIdx.x + blockDim.x*blockIdx.x;
    if (input[i]>0)
        result[i] = 1.f;
    else
        result[i] = 0.f;
}
```

What if different paths are taken within a warp?

Branch Divergence: Serialization

```
if (input[i]>0) result[i] = 1.f; else result[i] = 0.f;
```

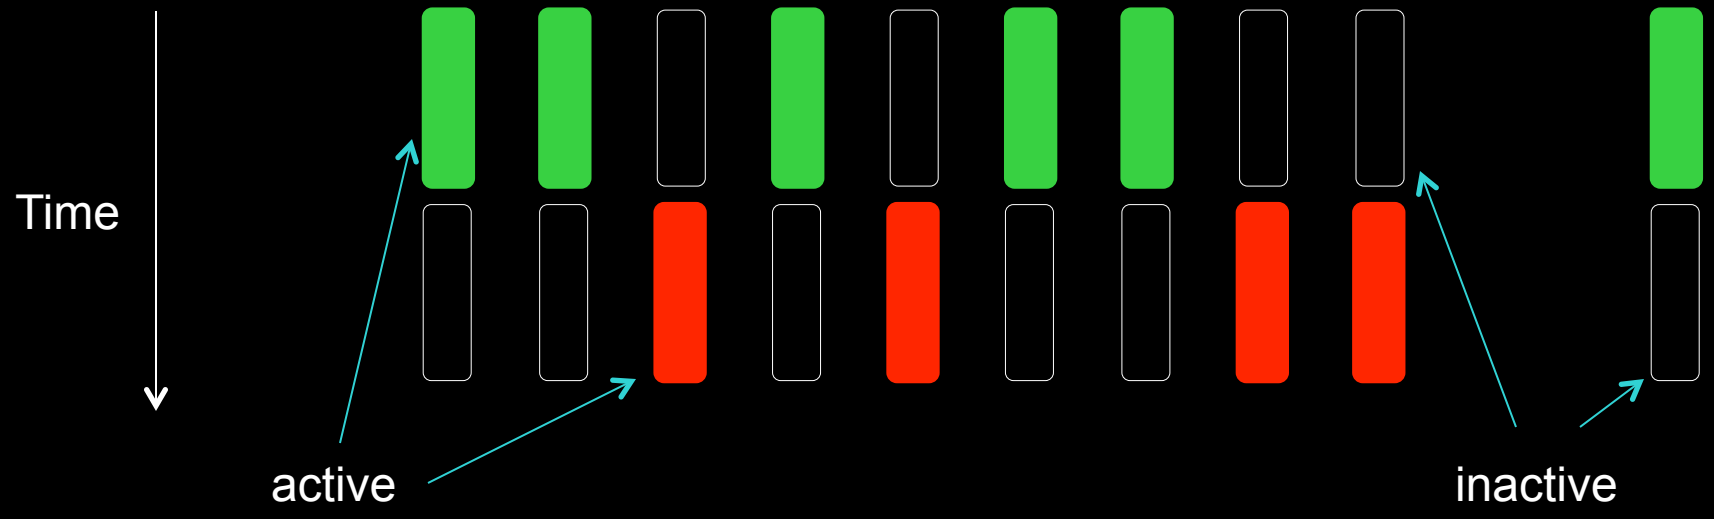
- If threads diverge within a warp execution is serialized
  - all 32 threads must execute the same instruction

- Each path is taken by each of the 32 threads
- Threads which do not correspond to this path are marked as inactive during execution

Branch Divergence: Serialization

```
if (input[i]>0) result[i] = 1.f; else result[i] = 0.f;
```

threadIdx.x:	0	1	2	3	4	5	6	7	8	...	31
input[i]:	7	23	-2	5	-1	66	24	-41	-3	...	18
input[i]>0:	T	T	F	T	F	T	T	F	F	...	T



Branch Divergence: Serialization

- Branch serialization occurs whenever the execution path within a warp diverges
  - `if / for / while / case`
- Potential divergence:
  - `if (input[x]>0) {...}`
  - `for(int i=0; i<num_iters[x]; i++) {...}`
- Divergence in different warps: No serialization
  - `if (threadIdx.x/32==0) {...}`

PITCHED ALLOCATION FOR 2D IMAGES

2D Images: Linear Allocation

- One can allocate 2D images as 1D-arrays and access in a linearized way: `img[x+w*y]`
- This works, but is in general suboptimal for CUDA
- For a `6*3 float` image, the addresses `&img[x+6*y]` are

48	52	56	60	64	68
24	28	32	36	40	44
0	4	8	12	16	20

- Read/write accesses are fastest when the starting address of each row is a multiple of a big power of 2
  - at least 128, or even 512
  - reason: requirement for memory coalescing, see later

2D Images: Pitched Allocation

- **Adding padding bytes at the end of each row resolves this**

64	68	72	76	80	84	88	92
32	36	40	44	48	52	56	60
0	4	8	12	16	20	24	28

- **The total new width in bytes is called pitch**
  - **here: pitch = 32 bytes (= `8*sizeof(float)`)**
  - **in general,** pitch != multiple of element size
    - example: 10*10 float3 array
    - sizeof(float3) = 12, w*sizeof(float3) = 120, pitch = 128

- **cudaMallocPitch (void **pointer, size_t *pitch,**
  size_t widthInBytes, size_t height);

2D Images: Pitched Allocation

- On host:

```
float *d_a;
size_t pitch;
cudaMallocPitch(&d_a, &pitch, w*sizeof(float), h);
```

- In kernel:

```
float value =
 *((float*)( (char*)a + x*sizeof(float) + pitch*y) );
```

- Copying: cudaMemcpy2D(...)
  - see NVIDIA Programming Guide

- For 3D-Data: cudaMalloc3D()

HOST-DEVICE MEMORY TRANSFER

Host-Device Memory Transfer

- Memcpy from device to host and vice versa is very slow
  - orders of magnitude slower than device-to-device
- Minimize transfers
  - leave data for as long as possible on GPU for processing
  - only transfer main inputs to GPU, and transfer main outputs back
- Group transfers
  - one large transfer much faster than many small ones
- Overlap transfers with kernel executions
  - if possible by hardware
  - uses pinned host memory and streams (see later)

Pinned Host Memory

- Enables highest memcpy performance
- Enables asynchronous memcpy (CC>=1.1)
- Enables direct access from GPU (CC>=1.1)

- `cudaMallocHost(void **pHost, size_t size, unsigned int flags);`
- `cudaFreeHost(void *ptr);`
- page-locked, allocating too much may degrade your system

- `flags = cudaHostAllocMapped`: direct access form GPU

```
void *pDev; cudaHostGetDevicePointer(&pDev, pHost, 0);
```

- `flags = 0`: default

Asynchronous Memory Copy

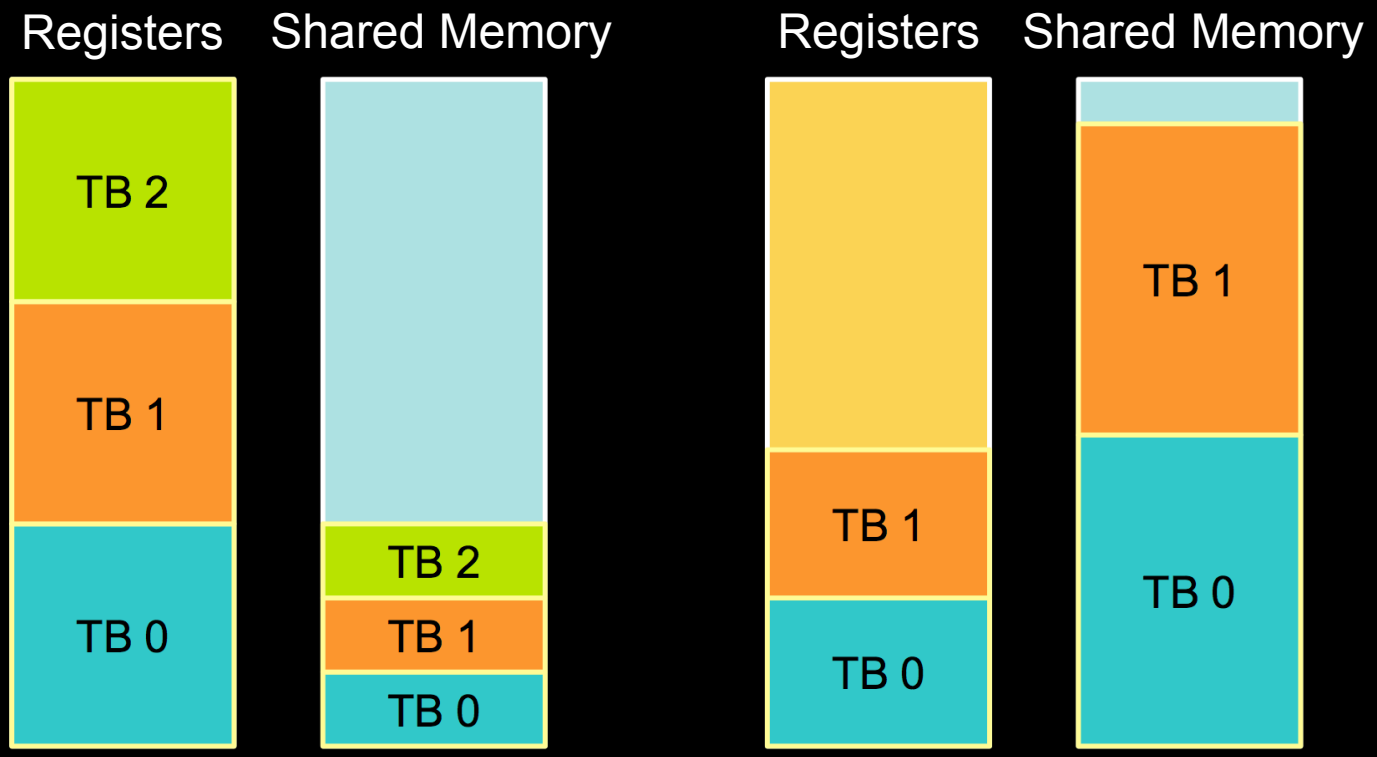
- Usual `cudaMemcpy` is blocking
  - waits until memcpy is done
- `cudaMemcpyAsync(dst, src, size, dir, 0);`
  - asynchronous, non-blocking
  - `cudaMemcpyDeviceToHost, cudaMemcpyHostToDevice`
  - `0` is the default stream (more later)
- Requirement: "pinned" host memory
  - allocated using `cudaMallocHost`

OCCUPANCY

Occupancy

- Multiprocessors (SMs) can have many more active threads than there are CUDA Cores
- High occupancy is important
  - if some threads stall, the SM can switch to others
- Pool of limited resources per SM
- Occupancy determined by
  - Register usage per thread
  - Shared memory per block

Resource Limits



- Each block grabs registers and shared memory
- If one or the other is fully utilized:
  - no more blocks per SM possible

Find Out Resource Usage

- Compile with `nvcc` option `-ptxas-options=-v`
- Per kernel registers and (static) shared memory:

```
ptxas info    : Compiling entry function '_Z10add_kernelPfPKfS1_i' for 'sm_10'
ptxas info    : Used 4 registers, 44 bytes smem
```

- Amount of resources per multiprocessor:
  - run `deviceQuery`

Optimize Algorithms for the GPU

- Maximize independent parallelism
- Maximize arithmetic density (math/bandwidth)
- Sometimes it's better to recompute than to cache
  - GPU spends transistors on computation, not memory
- Do more computation on the GPU to avoid costly data transfers
  - Even low parallelism computations can sometimes be faster than transfering back and forth to/from host
